ACKNOWLEDGEMENT

The success in this project would not have been possible but for the timely help and guidance rendered by many people. Our wish to express my sincere thanks to all those who has assisted us in one way or the other for the completion of my project.

Our greatest appreciation to my guide, **Vinisha Velthuru**, Department of Computer Science which cannot be expressed in words for his tremendous support, encouragement and guidance for this project.

We express our gratitude to Dr.N. Sirisha, Head of the Department for Computer Science Engineering for providing us with adequate facilities, ways and means by which we can complete this project-based Lab.

We thank all the members of teaching and non-teaching staff members, and who have assisted me directly or indirectly for successful completion of this project. Finally, I sincerely thank my parents, friends and classmates for their kind help and cooperation during my work.

.

Rushank Chaudhari-2320030105

ABSTRACT

In most healthcare organizations, there are copious amounts of data generated during the operation, and the organization utilizes different types of systems in the process. Data quality plays a major role in the analysis of data and also in the decision-making process, but the conventional approach to validating the data using several rules becomes complicated when dealing with increased volumes of data or complex data patterns. Here, the aim is to implement the AI-based approach for assessing the data quality using the Hadoop framework for big data.

The proposed system has been devised by taking advantage of the scalability provided by Hadoop; at the same time, machine learning techniques have also been employed, aiming at identifying data consistency, missing information, and data anomalies. Moreover, this system incorporates data processing, conducted in a distributed manner, in order to efficiently handle high-velocity as well as high-volume healthcare data. By incorporating AI technology regarding data anomalies, the system ensures efficient data processing, leading to a high degree of data trustworthiness, thereby enabling more effective decisions in the healthcare domain.

INTRODUCTION

The healthcare industry generates large volumes of operational data from multiple interconnected systems such as electronic health records, billing platforms, and monitoring systems. Maintaining data quality is essential for accurate analysis and effective decision-making; however, traditional rule-based validation methods become inefficient when handling large-scale and complex datasets.

To address this challenge, this project leverages Apache Hadoop for scalable and distributed data storage, enabling efficient handling of high-volume healthcare data. For data processing and querying, Apache Spark is used due to its fast in-memory computation and compatibility with modern systems, making it more suitable than traditional approaches.

The system integrates machine learning techniques, specifically anomaly detection using Isolation Forest, to automatically identify irregular patterns in system metrics such as workload, response time, error rates, and CPU usage. Unlike conventional methods, this AI-based approach adapts to data patterns and detects anomalies more effectively.

Additionally, the system includes a diagnostic component that classifies anomalies based on severity and provides root cause insights along with recommended actions. By combining big data technologies with AI-driven analysis, the proposed solution ensures improved data quality, early anomaly detection, and more reliable decision-making in healthcare operations.

PROBLEM DESCRIPTION AND OBJECTIVES

Modern healthcare systems generate vast amounts of operational data from multiple sources such as patient management systems, billing platforms, and monitoring tools. This data is often heterogeneous, high in volume, and continuously evolving. Ensuring its quality is a significant challenge, as traditional rule-based validation techniques are not scalable and fail to detect complex or hidden anomalies. Poor data quality can lead to incorrect analysis, inefficient operations, and unreliable decision-making in critical healthcare environments.

Although distributed frameworks like Apache Hadoop enable efficient storage and handling of large datasets, they do not inherently provide intelligent mechanisms for data quality assessment or anomaly detection. Additionally, legacy tools such as Hive face compatibility and performance issues in modern environments, limiting their effectiveness. This creates a need for a scalable, intelligent, and automated system that can both process large datasets and ensure their reliability.

The primary objectives of this project are:

- To design a scalable data processing system using Apache Hadoop for storing and managing large healthcare datasets.
- To utilize Apache Spark for efficient data processing, querying, and validation of healthcare operational data.
- To implement an AI-based anomaly detection mechanism using machine learning techniques (Isolation Forest) to identify irregular patterns in system metrics.
- To classify detected anomalies into severity levels (Healthy, Warning, Critical) for better interpretation and monitoring.
- To perform root cause analysis by identifying factors such as high CPU usage, increased response time, and error rates contributing to anomalies.
- To generate actionable recommendations that help improve system performance and data reliability.
- To provide visual insights through graphs and dashboards for better understanding of system health and trends.
- To enhance overall data quality and ensure reliable, data-driven decision-making in healthcare operations.

LITERATURE SURVEY

The rapid growth of healthcare data driven by digital technologies, electronic health records (EHRs), and IoT-enabled monitoring systems has created significant challenges in data management, quality assurance, and anomaly detection. Big data analytics has emerged as a critical solution for handling the volume, velocity, and variety of healthcare data. According to recent studies, healthcare data originates from multiple heterogeneous sources such as medical imaging, wearable devices, clinical records, and sensor networks, making traditional data processing methods insufficient for effective analysis. As a result, distributed frameworks like Hadoop and Spark have become essential for scalable data processing and analytics.

One of the key challenges in healthcare analytics is ensuring data quality and detecting anomalies that may indicate system failures, fraud, or abnormal patient conditions. Traditional rule-based approaches are limited in their ability to detect complex and hidden patterns in large datasets. To overcome these limitations, machine learning-based anomaly detection techniques have been widely explored. A comprehensive survey on anomaly detection in healthcare monitoring systems highlights the use of both supervised and unsupervised learning models, including Support Vector Machines (SVM), autoencoders, and hybrid approaches for detecting irregularities in physiological and sensor data. These methods have demonstrated effectiveness in identifying abnormal patterns in real-time healthcare environments.

In the context of big data, real-time anomaly detection has gained increasing importance. Habeeb et al. (2019) provide a detailed analysis of real-time big data processing technologies integrated with machine learning algorithms for anomaly detection. Their study emphasizes the role of distributed systems such as Hadoop, Spark, and cloud-based architectures in processing large-scale streaming data efficiently. The authors also propose a taxonomy that categorizes anomaly detection techniques based on data type, processing mode, and application domain, highlighting the need for hybrid models that combine big data processing with intelligent learning algorithms.

Isolation Forest has emerged as one of the most widely used unsupervised anomaly detection algorithms due to its efficiency and scalability. The algorithm works by isolating anomalies using random partitioning, making it particularly suitable for high-dimensional datasets. It has been shown to have low computational complexity and the ability to handle large datasets without requiring labeled data. Recent research has further enhanced the performance of Isolation Forest through hybrid and deep learning-based extensions, improving its ability to detect complex anomalies in big data environments.

Several studies have also explored the integration of machine learning techniques with distributed big data frameworks. For instance, a study on scalable anomaly detection highlights the effectiveness of algorithms such as Isolation Forest, streaming k-means clustering, and autoencoders in processing large datasets efficiently. These methods are particularly suitable for real-time applications due to their ability to adapt to evolving data patterns. Similarly, research on extending Isolation Forest using clustering techniques demonstrates improved detection accuracy when applied in distributed environments such as Spark-based architectures.

In healthcare-specific applications, anomaly detection plays a crucial role in identifying abnormal clinical events, system inefficiencies, and fraudulent activities. A study on anomaly detection in healthcare data emphasizes the importance of explainability in addition to detection accuracy. The proposed methods not only detect anomalies but also provide insights into why certain data points are considered anomalous, thereby improving interpretability and decision-making. Another research work highlights that manual anomaly detection is inefficient and error-prone, further reinforcing the need for automated machine learning-based solutions.

Data quality management is another critical aspect of healthcare analytics. Poor data quality can lead to incorrect predictions and unreliable decision-making. A recent study proposes an automated framework for detecting and correcting data quality anomalies using predictive models, demonstrating improved accuracy and reliability in large-scale datasets. This aligns with the growing need for integrating anomaly detection with data quality assessment in healthcare systems.

Furthermore, the application of Hadoop-based frameworks in healthcare anomaly detection has been explored in areas such as fraud detection. A study leveraging Hadoop's MapReduce framework demonstrates the ability to process millions of healthcare records efficiently and detect abnormal patterns in insurance claims data. This highlights the scalability and effectiveness of distributed systems in handling real-world healthcare data challenges.

Despite significant advancements, several challenges remain in the field of big data anomaly detection. These include handling high-dimensional data, ensuring real-time processing, maintaining data privacy, and improving the interpretability of machine learning models. Additionally, integrating multiple data sources and dealing with noisy or incomplete data continues to be a major concern in healthcare analytics.

In summary, the literature indicates that combining big data technologies with machine learning-based anomaly detection provides an effective solution for addressing the challenges of healthcare data analysis. Distributed frameworks such as Hadoop and Spark enable scalable data processing, while algorithms like Isolation Forest and deep learning models enhance anomaly detection capabilities. However, there is still a need for more integrated systems that combine data quality assessment, anomaly detection, and explainable AI to support reliable and efficient healthcare decision-making.

HARDWARE AND SOFTWARE REQUIREMENTS

HARDWARE SPECIFICATIONS:

The **AI-Assisted Data Quality and Anomaly Detection on Hadoop-Based Healthcare Operational Data** project does not require high-end hardware, as most of the data processing is handled using distributed frameworks such as Apache Hadoop and Apache Spark. However, a basic system configuration is necessary to run the local environment, execute scripts, and visualize outputs.

Processor
A system with an Intel Core i3 processor or equivalent is sufficient for running the project. For smoother performance while running Hadoop, Spark, and Python-based scripts, an Intel Core i5 or higher is recommended. The processor is mainly used for executing local services and managing multiple tools simultaneously.

RAM
A minimum of 4 GB RAM is required to run Hadoop, Spark, and Python environments. However, 8 GB RAM or more is strongly recommended to ensure efficient performance, as distributed frameworks and data processing tasks can consume significant memory.

Storage
At least 1 GB of free disk space is required for:

- Hadoop installation files
- Spark framework
- Dataset storage (CSV files)
- Temporary processing files and logs

Additional storage may be required depending on dataset size.

Graphics
No dedicated graphics card is required. Integrated graphics are sufficient, as the project focuses on data processing, analytics, and visualization rather than graphical rendering.

Operating System
The project is compatible with:

- Linux (recommended, e.g., Ubuntu)
- Windows (via WSL or direct setup)
- macOS

Linux-based systems are preferred for smoother Hadoop and Spark configuration.

SOFTWARE REQUIREMENTS:

The project uses a combination of open-source big data technologies and machine learning libraries to perform data processing, analysis, and anomaly detection.

Big Data Frameworks

- **Apache Hadoop**
  - Provides distributed storage using HDFS
  - Enables scalable handling of large healthcare datasets
- **Apache Spark**
  - Used for fast in-memory data processing
  - Supports SQL-based querying and analytics
  - Replaces traditional Hive-based querying due to better performance and compatibility
  -

Programming Language

- **Python (Version 3.8 or above)**
  Python is used for:
  - Data preprocessing
  - Machine learning (anomaly detection)
  - Visualization and reporting

Libraries and Frameworks

The following Python libraries are used:

- **Pandas** – Data manipulation and preprocessing
- **NumPy** – Numerical computations
- **Scikit-learn** – Machine learning (Isolation Forest for anomaly detection)
- **Matplotlib** – Data visualization (charts and graphs)
- **Seaborn** – Advanced visualizations (heatmaps, patterns)

These libraries are installed within a virtual environment for better dependency management.

Development Environment

- Hadoop local setup (pseudo-distributed mode)
- Spark Shell / Spark SQL
- Terminal (Linux shell) for running Hadoop and Spark services
- Text Editor (VS Code or Nano) for editing scripts
-

Visualization Tools

The project uses Python-based visualization libraries for representing results:

- **Matplotlib**
  - Bar charts (system health score)
- **Seaborn**
  - Heatmaps (severity analysis across time)

These visualizations help in understanding system behavior, anomaly trends, and performance patterns.

Execution Environment

The project is executed in a **local distributed setup**, where:

- Data is stored in Hadoop Distributed File System (HDFS)
- Data processing is performed using Spark
- Machine learning models run using Python locally

Summary

With the above hardware and software configuration, the healthcare data anomaly detection system can be executed efficiently. Since the heavy data processing is handled by distributed frameworks like Hadoop and Spark, the project does not require high-end hardware. The integration of big data technologies with machine learning ensures scalability, performance, and reliable detection of anomalies in healthcare operational data.

IMPLEMENTATION

The implementation of the AI-Assisted Data Quality and Anomaly Detection on Hadoop-Based Healthcare Operational Data project is carried out in multiple phases, integrating big data technologies with machine learning techniques. The system is designed as a complete pipeline starting from data generation to anomaly detection and visualization.

1. Data Generation

The first step involves generating a synthetic healthcare operational dataset using Python. A script (generate_healthcare_dataset.py) is used to create realistic system-level data such as:

- System name (EHR, Billing, etc.)
- Workload
- Response time
- Error count
- CPU usage
- Date

The dataset simulates real-world conditions by introducing:

- Workload fluctuations
- Peak usage scenarios
- Random anomalies

The generated data is stored in a CSV file (healthcare_ops.csv), which acts as the input for further processing.

2. Data Storage using Hadoop

The generated dataset is stored in the Hadoop Distributed File System (HDFS) using Apache Hadoop. Steps involved:

- Hadoop services are started (start-dfs.sh)
- HDFS directories are created
- Dataset is uploaded using HDFS commands

This allows the system to handle large datasets in a distributed and scalable manner.

3. Data Processing using Spark

Data processing is performed using Apache Spark, which provides fast in-memory computation.
Key steps:

- Spark shell is initialized
- A database (healthcare_db) is created
- A table (healthcare_ops) is created from the CSV file stored in HDFS

Spark SQL is used to:

- Query data
- Perform aggregations
- Validate data quality

This replaces traditional Hive-based querying due to better performance and compatibility.

4. Data Preprocessing

The dataset is loaded into Python using Pandas for preprocessing:

- Conversion of date column into datetime format
- Selection of relevant features for analysis
- Handling missing or inconsistent values

This prepares the data for machine learning processing.

5. Anomaly Detection using Machine Learning

Anomaly detection is implemented using the Isolation Forest algorithm from the scikit-learn library.
Steps involved:

- Selection of features (CPU usage, response time, workload, error count)
- Training the model on the dataset
- Predicting anomalies

The algorithm classifies each record as:

- Normal (1)
- Anomaly (-1)

This helps identify abnormal system behavior automatically.

6. Severity Classification

Detected anomalies are further categorized into severity levels:

- **HEALTHY** → Normal operation
- **WARNING** → Moderate issue
- **CRITICAL** → High-risk condition

The classification is based on threshold values such as:

- CPU usage > 90%
- Response time > 1500 ms
- High error count

This step improves interpretability of anomalies.

7. System Health Score Calculation

A health score is calculated for each system using the formula:
Health Score = (Normal Records / Total Records) × 100
Based on the score:

- Above 95% → Stable
- 85%–95% → Warning
- Below 85% → Critical

This provides a quantitative measure of system performance.

8. Visualization

Data visualization is performed using:

- Matplotlib

- Seaborn

The system generates:

1. **System Health Score Chart**
    - Bar chart showing health score of each system
2. **Severity Heatmap**
    - Displays daily system condition (Healthy, Warning, Critical)

These visualizations help in understanding trends and system behavior.

9. AI-Based Diagnostic and Recommendation System

An intelligent diagnostic module is implemented to:

- Identify root causes of anomalies:
    - Server overload
    - Performance degradation
    - Application failures
- Generate recommendations such as:
    - Increase system resources
    - Optimize queries
    - Fix application errors

This adds an AI-driven decision support layer to the system.

10. Execution Workflow

The complete execution flow of the system is:

1. Generate dataset
2. Store data in HDFS
3. Process data using Spark
4. Run anomaly detection using Python
5. Classify severity and compute health scores
6. Generate visualizations and reports

System: Appointment & Registration System
Total Anomaly Events: 8
- 4 Server Overload events detected
- 7 Performance Degradation events detected
- 2 Application Failure events detected
Recommended Actions:
  • Monitor API error rates continuously.
  • Implement load balancing across application servers.
  • Restart unstable services or APIs.
  • Implement traffic throttling.
  • Optimize database queries and reduce joins.
  • Tune JVM and application performance parameters.
  • Optimize background processing jobs.

System: Hospital Network & Log Systems
Total Anomaly Events: 35
- 8 Server Overload events detected
- 9 Performance Degradation events detected
- 3 Application Failure events detected
Recommended Actions:
  • Restart unstable services or APIs.
  • Inspect application logs for failures.
  • Tune JVM and application performance parameters.
  • Optimize background processing jobs.
  • Add indexing to frequently accessed tables.
  • Reduce unnecessary running services.
  • Optimize routing configurations.

Execution Completed Successfully.

RESULTS

The proposed system was successfully implemented using Hadoop, Spark, and machine learning techniques. The system was able to detect anomalies in healthcare operational data, classify their severity, and generate meaningful insights along with visual representations.

1. Dataset Summary

The dataset used for analysis was synthetically generated to simulate real-world healthcare system operations.

- Total Records: 1460
- Number of Systems: 4
- Time Duration: 365 days
- Attributes:
  - System Name
  - Workload
  - Response Time (ms)
  - Error Count
  - CPU Usage (%)
  - Date

The dataset included realistic workload variations and intentionally introduced anomalies to evaluate system performance.

2. Anomaly Detection Results

Anomaly detection was performed using the Isolation Forest algorithm.

- Total Records Analyzed: 1460
- Total Anomalies Detected: 73
- Percentage of Anomalies: 5.0%

The model successfully identified abnormal patterns based on deviations in CPU usage, response time, workload, and error rates. The detected anomalies correspond to potential system failures, performance bottlenecks, and unusual operational behavior.

3. System Health Analysis

The health score of each system was calculated based on the ratio of normal to anomalous records.

System Name	Total Records	Anomalies	Health Score	Status
EHR System	365	7	98.08%	Stable
Billing System	365	21	94.25%	Warning
Monitoring System	365	29	92.05%	Warning

System Name	Total Records	Anomalies	Health Score	Status
Inventory System	365	16	95.62%	Stable

The results indicate that while most systems operate efficiently, certain systems (especially Monitoring and Billing) show higher anomaly rates and require attention.

4. Visualization Results

(a) System Health Score Chart

A bar chart was generated to visualize the health score of each system. The chart uses color coding:

- Green → Stable
- Yellow → Warning
- Red → Critical

This visualization provides a quick overview of system performance and helps identify systems requiring improvement.

(b) Severity Heatmap

A heatmap was generated to represent daily system conditions across the monitoring period.

- Green → Healthy
- Yellow → Warning
- Red → Critical

The heatmap highlights temporal patterns and shows periods where systems experienced frequent warnings or critical conditions. This helps in identifying trends and recurring issues.

5. AI Diagnostic Results

The system performed root cause analysis on detected anomalies and identified the following:

- Server Overload Events: 28
- Performance Degradation Events: 19
- Application Failure Events: 26

The Monitoring System showed the highest number of overload and performance-related issues, indicating inefficient resource utilization.

6. Recommendations

Based on the detected anomalies and root cause analysis, the system generated the following recommendations:

- Increase server capacity or enable load balancing to handle high CPU usage
- Optimize database queries to reduce response time
- Improve error handling mechanisms to minimize application failures
- Perform regular system monitoring and maintenance

These recommendations help improve system performance and reduce future anomalies.

7. Key Observations

- Most anomalies occurred during peak workload periods
- High CPU usage strongly correlates with performance degradation
- Monitoring and Billing systems require optimization
- The AI model effectively detected hidden anomalies without predefined rules

CONCLUSION

The project titled *"*AI-Assisted Data Quality and Anomaly Detection on Hadoop-Based Healthcare Operational Data*"* successfully demonstrates the integration of big data technologies with machine learning for efficient data analysis and anomaly detection. The system was designed to handle large-scale healthcare operational data using Apache Hadoop for distributed storage and Apache Spark for fast and scalable data processing.

An AI-based approach using the Isolation Forest algorithm was implemented to detect anomalies in system performance metrics such as workload, response time, error count, and CPU usage. Unlike traditional rule-based methods, the machine learning model was able to identify hidden patterns and irregularities without requiring predefined conditions.

The system further enhanced interpretability by classifying anomalies into severity levels and computing system health scores. Visualizations such as health score charts and severity heatmaps provided clear insights into system behavior over time. Additionally, the AI diagnostic module performed root cause analysis and generated actionable recommendations, enabling proactive system management.

The results demonstrate that the proposed system is scalable, efficient, and capable of improving data quality and reliability. It can assist healthcare organizations in identifying system inefficiencies, preventing failures, and supporting better decision-making.

In conclusion, the integration of Hadoop, Spark, and machine learning provides a powerful solution for handling complex healthcare data. The system can be further extended to real-time monitoring, predictive analytics, and deployment in large-scale healthcare environments.
